## Reporting a One-Way Repeated Measures ANOVA

### Reporting Results using APA

- Three paired samples t-tests were used to make post hoc comparisons between conditions. A first paired samples t-test indicated that there was a significant difference between the number of pizza slices eaten before (M=3.0, SD=.76) and during (M= 6.3, SD=.71) the season;  $t(7) = 6.62, p = .000$ . A second paired samples t-test indicated that there was a significant difference between the number of pizza slices eaten during (M= 6.3, SD=.71) and after (M =1.4, SD=.52) the season;  $t(7) = 13.91, p = .000$ . A third paired samples t-test indicated that there was a significant difference between the number of pizza slices eaten before (M=3.0, SD=.76) and after (M =1.4, SD=.518) the season;  $t(7) = 6.18, p = .000$ .

Descriptive Statistics			
	Mean	Std. Deviation	N
Before	3.00	.756	8
During	6.25	.707	8
After	1.38	.518	8

Reporting Results using APA

Just fill in the blanks by using the SPSS output

There was a significant effect of time of season on eating pizza, Wilks' Lambda = .023,  $F(2, 6) = \dots, p = \dots$

## Reporting a Factorial ANOVA

### Reporting Results using APA

- A two-way analysis of variance was conducted on the influence of two independent variables (athlete type, age) on the number of slices of pizza eaten in one sitting. Athlete type included three levels (football, basketball, soccer players) and age consisted of two levels (younger, older). All effects were statistically significant at the .05 significance level except for the Age factor. The main effect for athlete type yielded an F ratio of  $F(2, 63) = 136.2, p < .001$ , indicating a significant difference between football players (M = 9.39, SD = 1.99), basketball players (M = 5.17, SD = 1.40) and soccer players (M = 3.97, SD = 1.53). The main effect for age yielded an F ratio of  $F(1, 63) = 2.7, p > .10$ , indicating that the effect for age was not significant, younger (M = 3.97, SD = 3.97) and older (M = 5.39, SD = 2.34). The interaction effect was significant,  $F(2, 63) = 13.36, p < .001$ .

Descriptive Statistics				
Dependent Variable:	Pizza_Slices	Mean	Std. Deviation	N
Football	Older	8.0000	.77469	11
	Younger	10.6667	1.92364	12
	Total	9.3913	1.99406	23
Basketball	Older	4.8182	1.36775	11
	Younger	5.5000	1.56670	12
	Total	5.1779	1.40299	23
Soccer	Older	3.3636	1.80404	11
	Younger	1.7500	.82158	12
	Total	2.5217	1.53355	23
Total	Older	5.3939	2.44440	33
	Younger	5.9722	3.97482	36
	Total	6.6917	3.18881	69

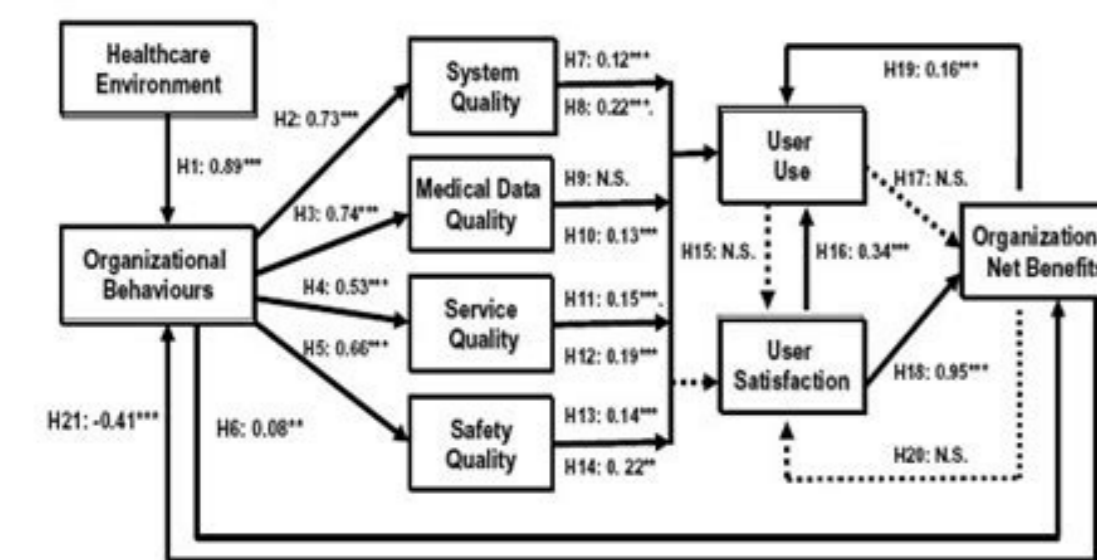

## Reporting a One-Way Repeated Measures ANOVA

### Reporting Results using APA

- Just fill in the blanks by using the SPSS output
- There was a significant effect of time of season on eating pizza, Wilks' Lambda = .023,  $F(2, 6) = \dots, p = \dots$

Multivariate Tests <sup>a</sup>						
Effect	Value	F	Hypothesis df	Error df	Sig.

How to report one way repeated measures anova apa. How to report one way anova apa. How to report one way repeated measures anova. How to report one-way anova results apa. Reporting one way repeated measures anova apa style.

Assumption # 7: Known as sphericity, the variations of the differences between the groups related to the factor within the subject for all groups of the factor between the subjects (ie, their factor within the subjects and the factor between subjects) must be equal. Therefore, if you believe that the mixed ANOVA is not the test you are looking for, you may want to consider a repeated measures of two VA ANOVA. Statistics versions of SPSS 25, 26, 27 and 28 (and the SPSS statistics subscription versions) Click Analyze> Linear Model> General> Repeated measures... Click on the button and the measurements will be presented Repeated: Dialog box options, as below is displayed: published with written permission from SPSS, IBM Corporation statistics. Complete confidentiality Your personal data are still confidential and will not be disclosed to the writer or other parties. Basically, this is the name of the dependent variable, which is cholesterol in this example. This SPSS statistics output will not determine if you have to return to the beginning of the entire mixed ANOVA process to try to make adjustments to your data so you can use this test (for example, "Transform" your data), but also n What SPSS statistics departure must be interpreted later (that is, depending on the results of the Mauchly sphere tests, which is used to test the assumption # 7). Procedure for carrying out a two-way mixed ANOVA, go to the interpretation results section. First, take a look at these steps: Step # 1: You must interpret the results of your assumption tests to make sure you can use a mixed ANOVA to analyze your data. Transfer pre, medium and published in the variables within the subjects (time): Table Highlighting all the variables (by clicking on them while holding the key pressed In the left box and clicking on the top button. You can find out about our improved content as a whole in our functions: Overhead, or more specifically, specifically, How we help with test assumptions in our features: Page of assumptions. Both the Mixed ANOVA and the repeated measures of two VIOS ANOVA involve two factors, as well as the desire to understand if there is an interaction between these two factors in the dependent variable. Each of these three groups of 20 participants received a different "condition": in a group, the participants did not change their current sedentary lifestyle (that is, this was group # 1, also called the "Control" group); in another group, the participants submitted to a low-intensity exercise training program that spent 1000 kcal per week (that is, this was group # 2, also called "treatment A"); The final group was subjected to a high-intensity exercise training program that also spent 1000 kcal per week, but, therefore, was exercised for less total time (that is, this was group # 3, I also called "treatment B"). STUDY DESIGN # 3 Your factor within the subjects consists of conditions (also known as treatments). You can learn more about the range and proportion variables in our article: Types of variables. You can do this by playing your profile plot. If you are not sure that statistical SPSS version is using, see our guide: Identification of your SPSS statistics version. After carrying out these simple main effects procedures in SPSS statistics, you must interpret the profile plots that occur, as well as the new SPSS statistics output in the Mauchly spherical test, the effects tests Within the subjects and the tables of pairs comparisons. Click on the button and repeated measures will be presented: multiple post hoc comparisons for the observed media dialog box, as shown below: published with the In writing of SPSS statistics, IBM Corporation. However, if there was a statistically significant interaction between its two factors in the dependent variable, you must perform some additional steps in SPSS statistics. Note: This particular configuration works for this example. We are obsessed with your privacy 1. Transfer before, half and publication in the variables within the subjects (time): Table highlighting all the variables (by clicking on them while holding down the MayAoS key) in the left box and by clicking on The upper button. In this case, enter "3", which represents Pre, Mid and Post, as shown below: Published with written permission from SPSS statistics, IBM Corporation. Before presenting these seven cases, it is not surprised if, when analyzing their own data using SPSS statistics, one or more of these assumptions is violated (ie, it is not met). In particular, it is important to realize that the mixed ANOVA is an OMNIBUS test statistic and can not tell you what specific groups within each factor were significantly different from SA. Take the plans of the tour and prices regain a mixed ANOVA compares the average differences between the groups that have been divided into two "factors" (also known as independent variables), where a factor is a factor "within subjects" and the other factor is a factor of "topics between subjects". Enter the level number: the number of time points (ie, the number of levels of the factor within the subject). In variable terms, the researcher wishes to know if there is an interaction between the group and time in cholesterol. The different interventions were stored in the variable, the group, where the "control" is the control group, "int\_1" is the low-intensity training intervention, and "int\_2" is the high intensity training intervention. It only tells you that at least two of the three groups were different. Click on the button and repeated measures will be presented: Dialog box options, as shown below: Published with written permission from SPSS statistics, IBM Corporation. Imagine that a researcher wants to determine if the levels of estrés between young people, middle-aged and older change the more time they are unemployed, as well as if there is an interaction between the age group and the length of unemployment at the levels of stress. You can get more information about our content improved in our functions: General description page. First, we introduce the example that is used in this guide. These groups form their "enters-subjects" factor. Therefore, the dependent variable was "cholesterol concentration", the factor within the subjects was "time" and the subjects factor was "conditions" (N.B., each of these variables is explained later). In the name of the factor within the subject: box, replace "factor1" with a more significant name for your factor within subjects. You can learn about our enhanced data configuration content in our functions: Data configuration page. Click on the button and get the following screen: Published with written permission from SPSS STATISTICS, IBM Corporation. This is not rare when working with real world data instead of examples of textbooks. The first related group consists of interactions at the beginning of the experiment, before the computerized spelling training, and the second related group consists of the same issues, but now at the end of the computerized training. Imagine that a health researcher wants to help suffer a chronic pain from back to reduce his levels of pain. Step # 3A: If you have a statistically significant interaction, informing the main effects within the effects tests within the subjects, the production of SPSS statistics can be cheated. Click on the button and you will be presented by the repeated measures dialog box, as shown below: published with the written permission of SPSS, IBM Corporation statistics. Since "the intensity of the exercise" is the factor "within the subjects," this means The 45 participants have to undergo the three treatments: the "High Intensity Exercise Program" (Treatment A), "Medium Intensity Exercises Program" (Treatment B) and "Low Intensity Exercise Program" (Treatment C). You do this analyzing analyzing Again the data to determine what is known as simple main effects (ie, instead of main effects). In our Improved Mixed Anova Guide, we: (a) I show you how to detect the atypical values using SPSS statistics, whether checking the atypical values in your "real data" or using "Student waste"; and (b) discussing some of the options you have to deal with atypical values. In the area of the exhibition, dial the descriptive statistics, the estimates of the size size and the homogeneity test check boxes, as shown below: published with written permission of SPSS, IBM Corporation In this guide "Rapid Start", we show you how to carry out a mixed ANOVA with post hoc tests using SPSS statistics, as well as the steps to which you should pass to interpret the results of this test. In addition, when we talk about the mixed only that require approximately normal data, this is because it is quite "robust" to the violations of normality, which means that the supposise may be a little violated and even thus provide results. Lidos. Click on the button and you will be presented by the repeated measures dialog box, as shown below: published with the written permission of SPSS, IBM Corporation statistics. All conditions (ie, control, treatment A and treatment B) lasted six months. Put an appropriate name in the name of the measure: box. Again, while this sounds a bit complicated, it can easily test this assumption in SPSS statistics using the Levene test for the homogeneity of variations. These three points of time (ie, the time point # 1, the time point # 2 and the time point # 3) represent the three factor groups within the subjects, if there is no interaction, follow-up tests can still be performed to determine if any change in stress levels was simply due to one of the factors (ie, time or age or age group). More specifically, these three different "conditions" (also known as "treatments") are a "high intensity exercise program" (treatment a), "medium intensity average" Program (Treatment B) and "Low Intensity Exercise Program" (Treatment C). During this period, the dependent variable, the "cholesterol concentration," was measured three times: "At the beginning of the experiment" (Time point # 1), "A half step through six months" (Time Point # 2) and "at the end of the experiment" (time of time # 3). In addition, if any of these main effects is statistically significant, you should interpret the output of relevant SPSS statistics of your post hoc tests in the pair comparisons table. It will end with the following screen: Published with written permission from SPSS, IBM Corporation statistics. Click on the button and you will be presented by repeated measures: Profile plots dialog box, as shown below: Published with written permission from SPSS, IBM Corporation statistics. SPSS statistics configuration In SPSS statistics In this example, there are three variables: (1) dependent variable, cholesterol, which is cholesterol concentration (in mmol / L); (2) The factor between the subjects, the group, which has three categories: "control" (control group), "int\_1" (treatment a) and "int\_2" (treatment B); and (3) the factor within the subjects, time, which has three categories: "Pre", "Mid" and "Post". Must do this because it is only appropriate to use a mixed ANOVA if Data "Pass" seven assumptions that are required for a mixed ANOVA to give it a valid result. Just remember remember if you do not execute the statistical tests in these assumptions correctly, the results you get when executing a mixed ANOVA could not be valid. In the name of the factor within the subject: box, replace "factor1" with a more significant name for your factor within the subject. Transfer time and "group \* time" (the interaction number) of factors (s) and factory interactions: Table to the visualization means for: Table Highlighting them and by clicking on the button. Now it is in a position to write all your results. Step # 2: You must make an initial judgment of what your data is seen and if you can expect a statement of statistically significant interaction. This will generate the output. Now that it has executed the general linear model- repeated measures... The main purpose of a mixed ANOVA is to understand if there is an interaction between these two factors in the dependent variable. In this example, replacing it with the name "Time", as this reflects the determined factor, time. You have to interpret the main effects for both factors (ie, the factor "within the subjects" and the factor "between the subjects"). At the end of the experiment, the psychologist uses a mixed ANOVA to determine if any change in depression (ie, dependent variable) is the result of the interaction between the intensity of the

exercise (ie, the "conditions / treatments", which It is within -Subicles factor) and GÀ % Nero (ie, a "characteristic" of the sample, which act as the factor between the subjects). If there is no interaction, follow-up tests can still be performed to determine if any change in back pain was simply owed to one of the factors (ie, conditions or time). In total, 45 participants participate in the experiment. In the upper menu, as shown below: Note: in version 27 and the version of SPSS statistics introduced a new appearance to its interface called "SPSS Light", replacing the previous search of versions 26 and previous versions, which was "Spass Standard". Click on the button and you will be presented by repeated measures: Profile plots dialog box, as shown below: Published with written permission from SPSS, IBM Corporation statistics. If it is not sure if a mixed ANOVA is appropriate, it is also possible that you also want to consider how it differs from a repeated measures of two VIOS ANOVA. Its factor among the subjects consists of conditions (also known as treatments). Next, in the number of levels: Table, enter the number of time points (ie, the number of levels of the factor within the subjects). In addition to showing how to do this in our improved mixed Anova guide, we also explain what you can do if your data fails this assumption (that is, if it fails it more than a bit). The dependent variable, "level of stress", is subsequently measured for four points of time, reflecting the factor within the subjects, "time" (ie, the levels of rubbing are measured "the first day that participants are unemployed "[Time Point # 1]," After a month of unemployment "[Time Point # 2]," After three months of unemployment "[Time Point # 3] and" After six months of unemployment "[Time Point # 4]). However, the order in which the participants receive each treatment differ, and the 45 participants are randomly divided into three groups: (a) 15 participants First submit to a treatment A (the "High Intensity Exercise Program"), followed by treatment B (the medium "intensity exercise program"), and finally treatment c (the "low intensity exercise program"); (b) another 15 participants begin with treatment B, followed by treatment C and finishing with treatment A; and (c) The final group of 15 participants start with treatment C, followed by treatment A, and finally, treatment B. This will activate the box Verification Compare main effects (that is, it will no longer be gray). Each of these three treatments (ie, treatment A, treatment B and treatment c) reflect the three groups of the Factor, "exercise intensity". Assumptions of SPSS statistics When choosing to analyze your data using a mixed ANOVA, much of the process involves verifying that the data you want to analyze can actually be analyzed using a mixed ANOVA. While it is not a difficult task, it will occupy most of the time when performing a mixed ANOVA. He would like to know if the computer training improved his spelling performance. The procedure changed in version 25 of SPSS statistics, we show how to carry out a mixed ANOVA in the SPSS 25, 26, 27 or 28 (or SPSS statistics subscription versions) or the version 24 Or a previous version of SPSS statistics. Alternatively, if none of these is appropriate, you can use our statistical test selector, which is part of our improved content, to determine what test is appropriate for its study design. Therefore, unlike the mixed ANOVA, the subjects are not separated into different groups based á €
